WOLFGANG TRUTSCHNIG,***

Abstract

We analyze copulas with a non-trivial singular component by using their Markov kernel representation. In particular, we provide existence results for copulas with a prescribed singular component. The constructions do not only help to deal with problems related to multivariate stochastic systems of lifetimes when joint defaults can occur with a non-zero probability, but even provide a copula maximizing the probability of joint default.

Keywords: Copula; Coupling; Disintegration Theorem; Markov Kernel; Singular measure.

2010 Mathematics Subject Classification: Primary 60E05

Secondary 28A50; 91G70.

1. Introduction

Copula models have become popular in different applications in view of their ability to describe a variety of different relationships among random variables [9, 8]. Such a growing interest also motivates the introduction of methodologies that go beyond classical statistical assumptions, like absolute continuity or smoothness of derivatives (i.e., conditional distribution functions), that sometimes may impose undesirable constraints

on the underlying stochastic model.

In order to fix ideas, consider the case when copulas are employed to describe the dependence among two (or more) lifetimes, i.e. positive random variables. Such models arise, at least, in two different domains. In engineering applications, joint models of lifetimes may be related to a system composed by several components that operates until some of their components work while others have already failed [4, 17, 16]. In portfolio credit risk modeling, instead, the lifetimes have the interpretation of default times (of firms, or obligors), while their copula serves to model the possible effect of one asset default on the probability of default of the other assets, which would require special care to avoid underestimation of the risk of the portfolio (see, e.g., [14]). In both cases, it is important to estimate the probability of the occurrence of a joint default, which means, in the case of a bivariate random vector (X, Y) , the probability of the event $\{X = Y\}$. Now, as stressed for instance in [15], if one requires that the event $\{X = Y\}$ has non-zero probability, then it would be important to select a copula for (X, Y) that has a singular component (i.e. it cannot be described via a single density function) and, in addition, its singular component spreads at least a part of its probability mass along a set determined by the marginals F_X and F_Y given by $\{(u, v) \in [0, 1]^2 : F_X^{-1}(u) = F_Y^{-1}(v)\}$, when F_X and F_Y are strictly increasing.

Motivated by these applications, it is hence desirable to provide a theoretical background for the study of copulas with singular components. In fact, as stressed for instance in [3], the related literature presents several statements that are not sound unless further assumptions are required. Here, we aim at clarifying several aspects about copulas with singular components. We provide examples and counter-examples that are of pathological nature, but may serve to warn against any simplistic thinking about the dependence structure. Finally, we present some existence results showing how to obtain copulas assigning positive mass to the graph of a function.

2. Basic definitions and properties of singular copulas

First of all, we recall some basic definition about copulas. Any 2-dimensional copula C is a multivariate distribution function on $[0, 1]^2$ whose univariate margins are uniformly distributed on $[0, 1]$. As such, it induces a probability measure μ_C on

the Borel sets $\mathcal{B}([0, 1]^2)$ of $[0, 1]^2$. Moreover, since μ_C cannot have atoms, in view of the Lebesgue decomposition theorem (see, e.g. [1, Theorem 2.2.6]), one has

$$\mu_C = \mu_C^{ac} + \mu_C^s,$$

where:

- μ_C^{ac} is a measure on $\mathcal{B}([0, 1]^2)$ that is absolutely continuous with respect to the d -dimensional Lebesgue measure λ_2 ;
- μ_C^s is a measure on $\mathcal{B}([0, 1]^2)$ that is singular with respect to the Lebesgue measure on $[0, 1]^2$, i.e. the probability measure is concentrated on a set B such that $\lambda_2(B) = 0$.

If $\mu_C^s([0, 1]^2) = 1 - \alpha > 0$, then C has a singular component of total mass equal to $1 - \alpha$.

The support of the singular component of a copula C is the complement of the union of all open subsets of $[0, 1]^d$ with μ_C^s -measure zero. In other words, it is the smallest closed set on which μ_C^s is concentrated. It is worth noticing that this support needs not be concentrated on graphs of functions (as in the case of Marshall–Olkin copulas) or segments (as for shuffles of Min). In fact, using the results in [7, 2], for any $s \in [1, 2]$, there exists a singular copula whose support has Hausdorff dimension s , as well as singular copulas with full support whose conditional distribution functions are continuous, strictly increasing and have derivative zero almost everywhere (see [20]). Therefore, up to simple cases, the mass of the singular component cannot be identified by looking at regions where the conditional distribution functions related to the copula (i.e. the derivatives) have jumps (compare with [10, pages 14–16] and [11, Theorem 8.1]). In the following section, we clarify these aspects by using the notion of a Markov kernel.

3. Singular copulas versus singular Markov kernels

The symbol $\mathcal{P}([0, 1]^2)$ will denote the family of all probability measures on $[0, 1]^2$. If $P^{(X,Y)} \in \mathcal{P}([0, 1]^2)$, then P^X (respectively, P^Y) denotes the marginal law defined on every Borel set $E \subset [0, 1]$ by $P^X(E) = P^{(X,Y)}(E \times [0, 1])$ (respectively, $P^Y(E) = P^{(X,Y)}([0, 1] \times E)$). Let \mathcal{C} denote the family of all two-dimensional copulas. For regular

conditional distributions, Markov kernels and disintegration theorems, we refer to [12]. Moreover, a mapping $K : [0, 1] \times \mathcal{B}([0, 1]) \rightarrow [0, 1]$ will be called *substochastic kernel* if $x \mapsto K(x, E)$ is Borel measurable in x for every $E \in \mathcal{B}([0, 1])$ and $E \mapsto K(x, E)$ is a measure of total mass less than or equal to one for every $x \in [0, 1]$. If $K(x, \cdot)$ is a probability measure on $[0, 1]$, then K will be called Markov kernel (see, for instance, [13]).

Given $A \in \mathcal{C}$ with $(X, Y) \sim A$, we denote (a version of) the regular conditional distribution of Y given X by $K_A(\cdot, \cdot)$ and refer to it as *Markov kernel of A* . It follows that, for every Borel set $F \in \mathcal{B}([0, 1])$ we have (with $F_x = \{y \in [0, 1] : (x, y) \in F\}$)

$$\int_{[0,1]} K_A(x, F_x) d\lambda(x) = \mu_A(F).$$

We start with the following simple observation.

Lemma 1. *Suppose that a copula C has a singular component, i.e. $\mu_C^s([0, 1]^2) = 1 - \alpha > 0$. If $(X, Y) \sim P^{(X, Y)} = \frac{1}{1-\alpha} \mu_C^s \in \mathcal{P}([0, 1]^2)$, then the marginal laws P^X and P^Y are absolutely continuous. If g_X denotes the density of P^X and K_C^s the Markov kernel of $\frac{1}{1-\alpha} \mu_C^s$ then we have*

$$\frac{1}{1-\alpha} \mu_C^s(E \times F) = P(X \in E, Y \in F) = \int_{[0,1]} K_C^s(x, F) g_X(x) d\lambda(x)$$

as well as

$$(1 - \alpha) K_C^s(x, [0, 1]) g_X(x) \leq 1$$

for λ -almost every $x \in [0, 1]$.

Proof. Let $E \in \mathcal{B}([0, 1])$, then we have

$$P^X(E) = \frac{1}{1-\alpha} \mu_C^s(E \times [0, 1]) \leq \frac{1}{1-\alpha} \mu_C(E \times [0, 1]) = \frac{1}{1-\alpha} \lambda(E)$$

so X is absolutely continuous (analogously, Y is absolutely continuous). The remaining part of the proof is a direct consequence of the Disintegration Theorem. ■

Thanks to the previous lemma, we can prove that the singularity of a copula depends on the singularity of the related Markov kernels, as stated in the following result.

Theorem 1. *Suppose that $C \in \mathcal{C}$. Then the following two conditions are equivalent:*

- (a) C is singular.

(b) There exists a set $\Lambda \in \mathcal{B}([0, 1])$ with $\lambda(\Lambda) = 1$ such that the measure $K_C(x, \cdot)$ is singular with respect to λ for every $x \in \Lambda$.

Proof.

(a) \Rightarrow (b): If C is singular then, by definition, there exists a set $N \in \mathcal{B}([0, 1]^2)$ with $\mu_C(N) = 1$ and $\lambda_2(N) = 0$. Applying disintegration to μ_C and λ_2 directly yields the existence of $\Lambda \in \mathcal{B}([0, 1])$ such that $\lambda(N_x) = 0$ and $K_C(x, N_x) = 1$ for every $x \in \Lambda$ whereby $N_x = \{y \in [0, 1] : (x, y) \in N\}$ denotes the x -cut of N .

(b) \Rightarrow (a): Suppose that C is not fully singular, i.e. $\mu_C^a([0, 1]^2) =: \alpha > 0$. Let k denote the density of μ_C^a . Without loss of generality we may assume that $\int_{[0, 1]} k(x, y) d\lambda(y) \leq 1$ for every $x \in [0, 1]$. If $\alpha = 1$, then the result follows immediately; so we examine the case when $\alpha \in (0, 1)$. Letting K_C^s denote the Markov kernel of $\frac{1}{1-\alpha} \mu_C^s$ and using Lemma 1, it follows that

$$\mu_C(E) = (1 - \alpha) \int_{[0, 1]} K_C^s(x, E_x) g(x) d\lambda(x) + \int_{[0, 1]} \int_{E_x} k(x, y) d\lambda(y) d\lambda(x) \quad (1)$$

for every $E \in \mathcal{B}([0, 1]^2)$. Define

$$K(x, F) = (1 - \alpha) K_C^s(x, F) g(x) + \int_F k(x, y) d\lambda(y)$$

for every $x \in [0, 1]$ and $F \in \mathcal{B}([0, 1])$, then $K(x, \cdot)$ is a finite measure on $\mathcal{B}([0, 1])$ and a measurable function in x for fixed F . Using equation (1) it is straightforward to verify that $K(x, [0, 1]) = 1$ for λ -a.e. $x \in [0, 1]$ so redefining $K(x, \cdot)$ (at most) on a set of measure zero yields a Markov kernel K_C of C . Since $\int_{[0, 1]^2} k d\lambda_2 = \alpha > 0$ we cannot have $(1 - \alpha) K_C^s(x, [0, 1]) g(x) = 1$ for λ -a.e. $x \in [0, 1]$. ■

As direct application of the results in [13] the Markov kernel K_C of an arbitrary copula $C \in \mathcal{C}$ can be decomposed into the sum of three substochastic kernels K_C^a, K_C^s, K_C^d , i.e.

$$K_C(x, E) = K_C^a(x, E) + K_C^s(x, E) + K_C^d(x, E) \quad (2)$$

for every $x \in [0, 1]$ and $E \in \mathcal{B}([0, 1])$. Thereby, the measure $K_C^a(x, \cdot)$ is absolutely continuous with respect to λ , the measure $K_C^s(x, \cdot)$ is singular with respect to λ and has no point masses, and $K_C^d(x, \cdot)$ is discrete for every $x \in [0, 1]$.

Examples of copulas whose Markov kernels show all three characteristics above are easily constructed. Consider the copula $A = \frac{1}{3}(\Pi_2 + S + T)$, whereby Π_2 is the

independence copula, S is one of the very singular copulas with full support from [20], and T is the singular copula with full support from [3]. Notice that all three copulas that appear in the expression of A have full support $[0, 1]^2$.

4. The singular mass of a copula and copulas whose singular mass is concentrated on the graphs of functions

In the previous section, we have investigated the main properties of the copulas with singular component with respect to the Markov kernel representation. Now, instead, we would like to raise the question whether we may use such representation in order to provide examples of copulas with a prescribed distribution of the singular component.

First, suppose that C is a copula, K_C is its Markov kernel, and that K_C is decomposed according to (2). Set

$$a_C(x) := K_C^d(x, [0, 1]) \quad (3)$$

for every $x \in [0, 1]$ (note that a_C depends on the concrete choice of the kernel and is therefore only defined uniquely λ -a.e.). Then a_C is measurable and we can (without unnecessary additional assumptions) calculate $\int_{[0,1]} a_C d\lambda$, i.e. the way how the discrete component spreads its mass. It turns out that, in general, the function a_C can be very irregular, as the following result shows (compare with [10, page 15]).

Theorem 2. *For every measurable function $f : [0, 1] \rightarrow [0, 1]$ there exists a copula C such that $a_C = f$.*

Proof. Let f be a measurable function such that $\|f\|_1 = \ell$. If $\ell \in \{0, 1\}$, then the result easily follows by considering the independence copula and the comonotonicity copula, respectively. Hence, assume that $\|f\|_1 \in (0, 1)$. We will construct a copula C with $a_C = f$ such that the singular component of C is concentrated on the diagonal $\Delta = \{(x, x) : x \in [0, 1]\}$ of the unit square. The procedure goes as follows. Let μ denote the measure on $\mathcal{B}([0, 1]^2)$ fulfilling $\mu(\Delta) = \mu([0, 1]^2)$ as well as $\mu([0, x]^2) = \int_{[0,x]} f d\lambda$ for every $x \in [0, 1]$. Let $S(x, y) := \mu([0, x] \times [0, y])$ the corresponding measure-generating function. Then S is symmetric and its marginal $F : [0, 1] \rightarrow [0, 1]$, given by $F(x) = S(x, 1) = \int_{[0,x]} f d\lambda$, is Lipschitz continuous (with Lipschitz constant one) and fulfills $F(1) = \|f\|_1 \in (0, 1)$. Setting $G : [0, 1] \rightarrow [0, 1]$ by $G(x) = x - F(x)$, we have

therefore another Lipschitz continuous measure-generating function fulfilling $G(0) = 0$ and $G(1) \in (0, 1)$. Define T and ϑ by

$$T(x, y) := \vartheta([0, x] \times [0, y]) := \frac{1}{G(1)} G(x)G(y)$$

for all $x, y \in [0, 1]$. Notice that such a T is obtained as product of its univariate marginals (so, it is constructed via the independence copula), however any other absolutely continuous copula can be used as well. It follows that ϑ is absolutely continuous with respect to λ_2 . Finally, considering

$$C(x, y) = S(x, y) + T(x, y)$$

it follows immediately that C is a copula whose singular component is μ . Applying disintegration we directly get $a_C = f$ λ -a.e. Since the Markov kernel of a copula is only defined uniquely a.e., the proof is completed. ■

Using essentially the same idea of the previous proof we can show that, for every transformation $T : [0, 1] \rightarrow [0, 1]$ being non-singular (i.e. the push-forward λ^T is absolutely continuous w.r.t. λ), we can find a copula A such that the corresponding kernel K_A fulfills $K_A(x, \{Tx\}) > 0$ for every $x \in [0, 1]$. In other words, the singular components of copulas can be concentrated on the graphs of arbitrary non-singular transformations.

Theorem 3. *For every non-singular transformation $T : [0, 1] \rightarrow [0, 1]$ there exists a copula A such that the singular component of A is concentrated on the graph $\Gamma(T)$ of T . Moreover, $K_A(x, \{Tx\}) > 0$ for every $x \in [0, 1]$.*

Proof. Suppose that $T : [0, 1] \rightarrow [0, 1]$ is non-singular and let f denote the density of λ^T with respect to λ . Define $a : [0, 1] \rightarrow [0, 1]$ by

$$a(x) = \begin{cases} 1 & \text{if } f \circ T(x) \leq 1, \\ \frac{1}{f \circ T(x)} & \text{if } f \circ T(x) > 1. \end{cases} \quad (4)$$

Using Cauchy-Schwarz inequality it is straightforward to verify that $\int_{[0,1]} a \, d\lambda = 1$ if and only if T is λ -preserving. Since for λ -preserving T the (completely dependent) copula A with the kernel $K_A(x, F) = \mathbf{1}_F(Tx)$ has the properties stated in the theorem

we can focus on the case $\int_{[0,1]} a d\lambda < 1$. Let δ_z denoting the Dirac measure in z for every $z \in [0, 1]$. Obviously $K^d : [0, 1] \times \mathcal{B}([0, 1]) \rightarrow [0, 1]$, defined by

$$K^d(x, F) := a(x) \delta_{Tx}(F) = a(x) \mathbf{1}_F(Tx),$$

is a substochastic kernel. Its induced measure μ , given by

$$\mu(E \times F) = \int_E a(x) \delta_{Tx}(F) d\lambda(x),$$

fulfills $\mu([0, 1]^2) = \int_{[0, 1]} a d\lambda \in (0, 1)$. Let S denote the corresponding measure-generating function and F, G the measure-generating functions of the marginals μ^{π_1}, μ^{π_2} . It is straightforward to verify that $F(1) = G(1)$. Moreover, F has density a and G has density g given by

$$g(x) = f(x) \mathbf{1}_{[0, 1]}(f(x)) + \mathbf{1}_{(1, \infty)}(f(x)),$$

i.e. both densities only take values in $[0, 1]$. As direct consequence $\hat{F}, \hat{G} : [0, 1] \rightarrow [0, 1]$, defined by

$$\hat{F}(x) = \frac{x - F(x)}{1 - F(1)}, \quad \hat{G}(y) = \frac{y - G(y)}{1 - G(1)}$$

are absolutely continuous distribution functions. Hence

$$R(x, y) := \frac{1}{1 - F(1)}(x - F(x))(y - G(y))$$

defines a two-dimensional measure-generating function. (Notice that such a R is obtained as product of its univariate marginals, however any other absolutely continuous copula can be used as well to construct it). Finally, it easily follows that $A_T := S + R$ is a copula with the desired properties. ■

If we replace function a in (4) by any other measurable function b with $0 < b(x) \leq a(x)$ λ -a.e. on $[0, 1]$ we may obtain other copulas that concentrate mass on $\Gamma(T)$. Remarkably, the copula A_T constructed in the proof of Theorem 3 does not only fulfill $K_A(x, \{Tx\})$ for every $x > 0$, but it even assigns maximum possible mass to the graph $\Gamma(T)$.

Theorem 4. *Let $T : [0, 1] \rightarrow [0, 1]$ be a non-singular transformation and let A_T denote the copula constructed in the proof of Theorem 3. Then we have $\sup_{B \in \mathcal{C}} \mu_B(\Gamma(T)) = \mu_{A_T}(\Gamma(T))$.*

Proof. As above, let f denote of density of λ^T , let a be defined according to equation (4) and set $F := f^{-1}((1, \infty))$. Suppose that $B \in \mathcal{C}$ fulfills $\mu_B(\Gamma(T)) > \mu_{A_T}(\Gamma(T))$ and set $b(x) := K_B(x, \{Tx\})$ for every $x \in [0, 1]$. Since b cannot be strictly greater than a on $T^{-1}(F^c)$, it follows that $\int_{T^{-1}(F)} b d\lambda > \int_{T^{-1}(F)} a d\lambda$, from which we get

$$\begin{aligned} \lambda(F) &= \int_{[0,1]} K_B(x, F) d\lambda(x) \geq \int_{[0,1]} b(x)\delta_{Tx}(F)d\lambda(x) = \int_{T^{-1}(F)} b d\lambda \\ &> \int_{T^{-1}(F)} a d\lambda = \int_{[0,1]} a(x)\delta_{Tx}(F)d\lambda(x) = \int_{[0,1]} \frac{1}{f \circ T(x)} \mathbf{1}_F(T(x)) d\lambda(x) \\ &= \int_{[0,1]} \frac{1}{f(y)} \mathbf{1}_F(y)f(y) d\lambda(y) = \lambda(F). \end{aligned}$$

Hence we can not have $\mu_B(\Gamma(T)) > \mu_{A_T}(\Gamma(T))$. ■

Theorem 3 implies the following result.

Corollary 1. *Suppose that $T_1, T_2, T_3, \dots : [0, 1] \rightarrow [0, 1]$ are non-singular transformations. Then there exists a copula $A \in \mathcal{C}$ such that $K_A(x, \{T_i x\}) > 0$ for every $x \in [0, 1]$ and every $i \in \mathbb{N}$.*

Proof. For every $i \in \mathbb{N}$ let $A_i := A_{T_i}$ denote the copula according to Theorem 3. Then the copula $B := \sum_{i=1}^{\infty} \frac{1}{2^i} A_i$ has the stated property. ■

Finally, we discuss an interesting application. Following [15], suppose that X, Y are two lifetimes with continuous and strictly increasing distribution functions F_X and F_Y . Set $T(x) := F_Y \circ F_X^{-1}(x)$. Then Theorem 4 ensures that the copula A_T is such that $\mathbb{P}(X = Y)$ is maximal. In other words, a joint default is most likely to occur under this dependence structure. Figure 1 shows a random sample from the copula A_T when $T(x) = x^2$. Notice that such problems are popular in the coupling literature, although they usually require additional assumptions like the existence of marginal densities for X and Y (see [18]).

5. Conclusions

We have analyzed the class of copulas with a non-trivial singular component by using their Markov kernel representation. In particular, we provide existence results about copulas with prescribed singular component in a very general setting. We argue

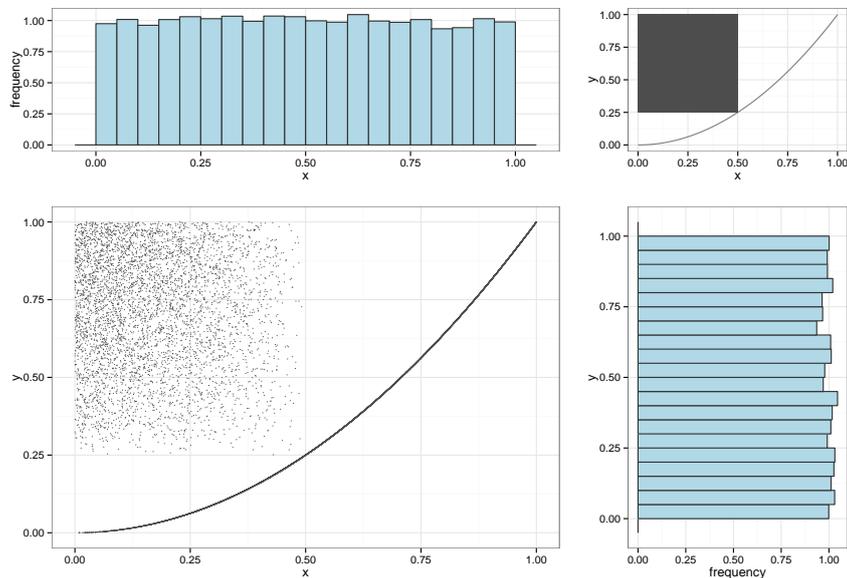

FIGURE 1: Scatterplot of a bivariate sample of size 20000 generated by the copula A_T from Theorem 4 with $T(x) = x^2$ (lower left), including the marginal histograms as well as the support of the copula (upper right).

that such investigations may help to deal with copulas in many problems related to stochastic systems of lifetimes.
